■ Surrogate assisted design optimization
■ Summary
Since the dawn of the space era, the satellites in geosynchronous orbit have gained great interests because of the merits in communications, earth observation, navigation, etc. **State-of-the-art GEO satellites are capable of using electric thrusters to perform all propulsive tasks like orbit-raising and station-keeping.** Compared with conventional GEO satellites using the all-chemical or hybrid propulsion systems, **all-electric GEO satellite can save considerable amount of propellant owing to the superior efficiency of electric propulsion (EP) system**, which results in significant reduction of the launch cost and additional payloads.
Introduction

Although all-electric GEO satellites consume much less propellant than the competitive chemical ones, it requires extremely long transfer time due to the low thrust produced by electric thrusters. Not only does this delay the deployment of GEO satellites, but also result in serious radiation damage of devices like solar arrays caused by the prolonged transfer time within the Van Allen belts. It requires that the design of geosynchronous transfer orbit, station-keeping strategy, power, attitude control, propulsion, and structure subsystems, etc. should be considered simultaneously.

Hence, the designers must make tradeoffs among different subsystems (disciplines) of an all-electric satellite. **Multidisciplinary design optimization (MDO)** is therefore preferred to deal with the satellite system design problems. MDO was originally proposed by Sobieski, which was defined as “a methodology for the design of complex engineering systems and subsystems that coherently exploits the synergy of mutually interacting phenomena” by NASA’s Langley Research Center.
A surrogate assisted MDO framework is utilized to handle the all-electric GEO satellite multidisciplinary design optimization problem.
Introduction

AETS MDO problem definition

Multidisciplinary modeling for AETS

Surrogate assisted design optimization

Summary
The studied all-electric telecommunication satellite (AETS) is a kind of GEO communication satellite. AETS comprises payload module, service module, solar arrays, and payloads. **AETS uses four ion thrusters mounted on the bottom of the satellite to execute geosynchronous transfer and GEO station keeping maneuvers.** The ion thrusters can provide a maximum thrust of 200mN with 4.5kW power and 4000s specific impulse.
In view of the typical characteristics of all-electric GEO satellite, we mainly choose the geosynchronous transfer, GEO station-keeping, solar power, and structure as the modeled disciplines for AETS MDO problem. The coupling relationship for the MDO problem is organized in design structure matrix (DSM).

Design Structure Matrix of the MDO problem

\[
\begin{align*}
\min M_{\text{satellite}} &= f(X), \quad X = [x_1, x_2, x_3, x_4]^T \\
\text{s.t.} \quad &D_i(x_i, y_i, y_{ij}) = 0, \quad i = 1, 2, 3, 4 \\
\quad &C_i(x_i, y_i, y_{ij}) \leq 0, \quad i = 1, 2, 3, 4
\end{align*}
\]

Multidisciplinary modeling for AETS

- Geosynchronous transfer discipline modeling

A two-stage electric propulsion transfer is utilized to determine the geosynchronous transfer orbit (GTO) to accomplish low continuous thrust GEO insertion of the satellite.

\[
\begin{align*}
\frac{da}{dt} &= \frac{2}{n\sqrt{1-e^2}} \left( F_e \sin f + F_T (1 + e \cos f) \right) \\
\frac{de}{dt} &= \frac{\sqrt{1-e^2}}{na} \left( F_R \sin f + F_T (\cos f + \cos E) \right) \\
\frac{di}{dt} &= \frac{r \cos u}{na^2 \sqrt{1-e^2}} F_N \\
\frac{d\Omega}{dt} &= \frac{r \sin u}{na^2 \sqrt{1-e^2} \sin i} F_N \\
\frac{d\alpha}{dt} &= \frac{\sqrt{1-e^2}}{nae} \left( -F_R \cos f + F_T \left(1 + \frac{r}{p}\right) \sin f \right) - \cos i \frac{d\Omega}{dt} \\
\frac{dM}{dt} &= n - \frac{1-e^2}{nae} \left( -F_R (\cos f - 2e \frac{r}{p}) + F_T (1 + \frac{r}{p}) \sin f \right)
\end{align*}
\]

In the first stage, the eccentricity is reduced to 0.

In the second stage, the semi-major axis is increased to 42166km and the inclination is reduced to 0°.
GEO station-keeping discipline modeling

The GEO position-keeping discipline models the **north/south station keeping (NSSK)** and **east/west station keeping (EWSK)** maneuvers implemented by EP system to determine the thruster installation configuration. A completed EP position keeping period lasts for two weeks with seven short periods of two days.

\[
\begin{align*}
\Delta D &= -\frac{3}{a_s} \Delta V_T \\
\Delta \lambda &= -2 \frac{\Delta V_R}{V_s} \\
\Delta e_x &= \frac{\Delta V_R}{V_s} \sin l + 2 \frac{\Delta V_T}{V_s} \cos l \\
\Delta e_y &= -\frac{\Delta V_R}{V_s} \cos l + 2 \frac{\Delta V_T}{V_s} \sin l \\
\Delta i_x &= \frac{\Delta V_N}{V_s} \cos l \\
\Delta i_y &= \frac{\Delta V_N}{V_s} \sin l
\end{align*}
\]

Illustration of thrusters on the bottom and GEO position keeping strategy
Solar power discipline modeling
The solar power discipline computes the area of solar arrays to provide sufficient available power.

\[ P_0 = (1 - p_r)S_0XX_sX_eX_0A_{sa}\eta F_c(\beta_p\Delta T + 1)\cos \chi \]

The NASA AP8 Approximation Model is utilized to compute the omnidirectional radiation flux of protons, the non-ionizing energy loss (NIEL) of solar arrays (Gallium Arsenide) is computed by the interpolation result of experimental data.

\[ \psi(L, \lambda, E) = a(L, E)e^{-b(L,E)l^2} \]

\[ L = \frac{r}{R \cos^2 l} \]

\[ a(L, E) = a_0e^{a_1E + a_2(a_3 + L)^2} \]

\[ b(L, E) = b_0 + b_1E + b_2L + b_3EL + b_4EL + b_4L^2 + b_5L^3 \]

\[ D_d(E) = \phi(E)NIEL(E) \]

\[ p_r = K \log(1 + \frac{D_d}{D_x}) \]
Structure discipline modeling

The structure discipline establishes the structural finite element (FE) model of the satellite based on the given configuration to obtain the mass properties and natural frequencies. The structural FE model of the all-electric GEO satellite is established by Patran/Nastran including 6235 elements and 5991 nodes.

Surrogate assisted design optimization

- Review of ARSM-ISES

To reduce the computational cost in solving MDO problems with expensive functions, surrogate-based analysis and optimization (SBAO) technologies have been widely employed. In SBAO, a surrogate model is constructed to represent the true computationally expensive analysis model or multidisciplinary design analysis (MDA) process for simulation-based optimization.

The adaptive response surface method with intelligent space exploration strategy (ARSM-ISES) is used to solve the optimization problem.
Surrogate assisted design optimization

**Build design optimization model**
- Design Variables
- Objective Constraints
- Initial Design Space

1. Set initial conditions
2. LHD sampling
3. Invoke analysis model at the samples
4. Build RSM using current samples
5. Obtain the potential optimum of the iterative metamodel using GA
6. Invoke analysis model at the potential optimum
7. The termination criterion is checked, if satisfied, turn to step 9, otherwise go to step 8
8. Generate new samples using SDS method
9. The process terminates

**Flowchart of ARSM-ISES**
Surrogate assisted design optimization

- **Optimization Results**

The optimization yields **66.1kg** decrease in total mass, i.e., about **5.4%** of the satellite components being optimized.

Introduction

AETS MDO problem definition

Multidisciplinary modeling for AETS

Surrogate assisted design optimization

Summary
A surrogate assisted MDO framework consisting of MDO problem definition, disciplinary modeling, and surrogate assisted optimization, is introduced to efficiently implement the state-of-the-art all-electric GEO satellite system design.

A surrogate-based optimization method is utilized to reduce the computational cost of the satellite MDO problem. The total transfer time is reduced by 21.7%, while the total mass yields a 66.1kg decrease after optimization. The reduced mass leads to a lighter satellite with lower launch cost, and it could also be dedicated to additional payloads which means more revenue from customers’ perspective.

The optimization results illustrate that the proposed surrogate assisted MDO framework is feasible and effective to improve the quality and efficiency of all-electric GEO satellite system design. The work could be referred for further all-electric spacecraft system research. In future work, we will try to apply this proposed framework to other spacecraft systems design and optimization.
